Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

`true + 41` →

`true + "!"` →

`"the answer is " + 42` →

`"the answer is " + 4 + (1+true)` →

`x + " vs " + (1+x)` →

`"result: " + ("test"?42:true)` →

`"result: " + (x?42:true)` →

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

`true + 41` → 42

`true + "!"` →

`"the answer is " + 42` →

`"the answer is " + 4 + (1+true)` →

`x + " vs " + (1+x)` →

`"result: " + ("test"?42:true)` →

`"result: " + (x?42:true)` →

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

<code>true + 41</code>	→	<code>42</code>
<code>true + "!"</code>	→	<code>"true!"</code>
<code>"the answer is " + 42</code>	→	
<code>"the answer is " + 4 + (1+true)</code>	→	
<code>x + " vs " + (1+x)</code>	→	
<code>"result: " + ("test"?42:true)</code>	→	
<code>"result: " + (x?42:true)</code>	→	

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

<code>true + 41</code>	→	<code>42</code>
<code>true + "!"</code>	→	<code>"true!"</code>
<code>"the answer is " + 42</code>	→	<code>"the answer is 42"</code>
<code>"the answer is " + 4 + (1+true)</code>	→	
<code>x + " vs " + (1+x)</code>	→	
<code>"result: " + ("test"?42:true)</code>	→	
<code>"result: " + (x?42:true)</code>	→	

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

<code>true + 41</code>	→	<code>42</code>
<code>true + "!"</code>	→	<code>"true!"</code>
<code>"the answer is " + 42</code>	→	<code>"the answer is 42"</code>
<code>"the answer is " + 4 + (1+true)</code>	→	<code>"the answer is 42"</code>
<code>x + " vs " + (1+x)</code>	→	
<code>"result: " + ("test"?42:true)</code>	→	
<code>"result: " + (x?42:true)</code>	→	

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

<code>true + 41</code>	→	<code>42</code>
<code>true + "!"</code>	→	<code>"true!"</code>
<code>"the answer is " + 42</code>	→	<code>"the answer is 42"</code>
<code>"the answer is " + 4 + (1+true)</code>	→	<code>"the answer is 42"</code>
<code>x + " vs " + (1+x)</code>	→	<code>"undefined vs NaN"</code>
<code>"result: " + ("test"?42:true)</code>	→	
<code>"result: " + (x?42:true)</code>	→	

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

<code>true + 41</code>	→	<code>42</code>
<code>true + "!"</code>	→	<code>"true!"</code>
<code>"the answer is " + 42</code>	→	<code>"the answer is 42"</code>

<code>x + " vs " + (1+x)</code>	→	<code>"undefined vs NaN"</code>
<code>"result: " + ("test"?42:true)</code>	→	<code>"result: 42"</code>
<code>"result: " + (x?42:true)</code>	→	

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

<code>true + 41</code>	→	<code>42</code>
<code>true + "!"</code>	→	<code>"true!"</code>
<code>"the answer is " + 42</code>	→	<code>"the answer is 42"</code>
<code>"the answer is " + 4 + (1+true)</code>	→	<code>"the answer is 42"</code>
<code>x + " vs " + (1+x)</code>	→	<code>"undefined vs NaN"</code>
<code>"result: " + ("test"?42:true)</code>	→	<code>"result: 42"</code>
<code>"result: " + (x?42:true)</code>	→	<code>"result: true"</code>

Dynamic typing and implicit casts

In JS, which result are you expecting from the following expressions ?
(x not initialised)

<code>true + 41</code>	→	<code>42</code>
<code>true + "!"</code>	→	<code>"true!"</code>
<code>"the answer is " + 42</code>	→	<code>"the answer is 42"</code>
<code>"the answer is " + 4 + (1+true)</code>	→	<code>"the answer is 42"</code>
<code>x + " vs " + (1+x)</code>	→	<code>"undefined vs NaN"</code>
<code>"result: " + ("test"?42:true)</code>	→	<code>"result: 42"</code>
<code>"result: " + (x?42:true)</code>	→	<code>"result: true"</code>

Dynamic types are only known at execution time
and the operator "+" behave differently depending on the type

Not the case in C that does the casts statically.

Casts are implicit

In JS, "true+3" triggers an implicit cast

The boolean true is casted in the number 1.

Instruction	semantic	before	after
BoToNb	if Pop then Push(1) else Push(0)	b:stk	n:stk
NbToBo	Push(Pop \neq_f 0)	n:stk	b:stk

Those instruction allows for explicit cast in the assembly

CsteBo True
BoToNb
CsteNb 3
AddiNb

How to cast from variable ?

A same variable can contain a number or a boolean, how to know which cast performing ? Two solutions :

Static type inference

Impossible in JS : `x = true;`
`if (b) x=0;`
`x+3;`

Testing types dynamically

We will naively
 test each type all the time
 (partial inference and JIT help)

Instruction	semantics	before	after
TypeOf	Peak a value, returns 0 on a Boolean, 1 on a Number...	v:stk	n:v:stk
Cases	<code>PC := PC + Floor(Pop) + 1;</code>	n:stk	stk
Cases p	<code>PC := PC + p * Floor(Pop) + 1;</code>	n:stk	stk

A more reasonable code for sums

Instruction	semantique	before	after
TypeOf	Peak a value, return 0 son a Booleen, 1 on a Number...	v:stk	n:v:stk
Cases	PC := PC + Floor(Pop) + 1;	n:stk	stk

$$[[e_1 + e_2]] =$$

[[e ₁]]	
TypeOf	
Cases	0 1
BoToNb	← 0
[[e ₂]]	← 1
TypeOf	
Cases	0 1
BoToNb	← 0
AddiNb	← 1

Cases instruction : a relatively comon but dangerous instruction

The instruction Cases is a jump which offset is gotten dynamically, replacing many “if” by a unic instruction.

Cases	$PC := PC + Pop + 1;$	n:stk	stk
Cases p	$PC := PC + p * Pop + 1;$	n:stk	stk

It is used for

- dynamic types
- switches in C,
- pattern-matching,
- brutal optimisations

Default: in order to correctly align, one have to add Noop (or any other instruction) that are useless lines.

To understand how powerfull it can be: play TIS100

The Undefined type

Non initialised variable in JS

In JS if a variable is used before being initialised, its value is undefined which type is Undefined.

In the mini-JS machine

Idem : the value undefined is pushed.
Additionally, TypeOf on an Undefined results in the number 3.

The type “Undefined” is in the project !

In the project, the undefined case has to be treated, so that their behavior mimic that of JS.

Type Strings are not mandatory in the project
Treated in TD.

Complexity of the assembly language vs complexity of the virtual machine

Dynamic types

- complex assembly code,
- simple machine,
- everything by hand.

Functions, ...

- simple assembly code,
- instructions/structures
abstrait and complex.

Complexity of the assembly language vs complexity of the virtual machine

Dynamic types

- complex assembly code,
- simple machine,
- everything by hand.

Functions, ...

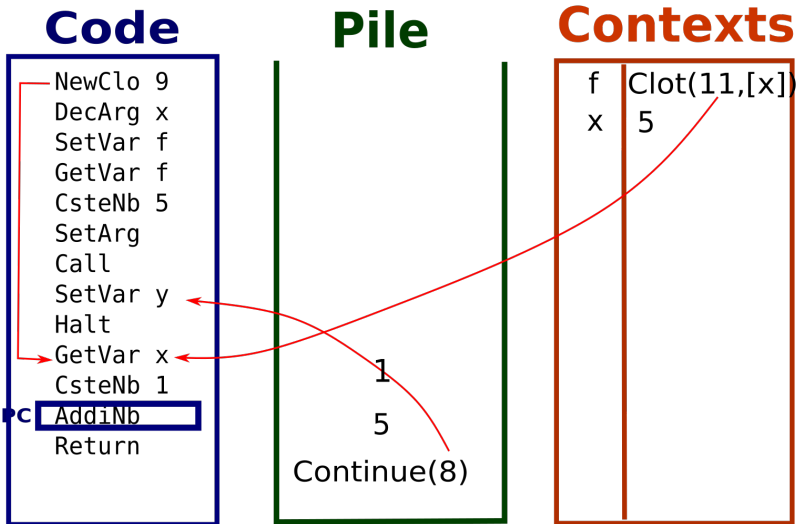

- simple assembly code,
- instructions/structures
abstrait and complex.

Good practice in programming: not to mix codes that are

- low level / dirty / opimised and those that are
- high level / complexe / efficient.

↪ our choice is pedagogical but do not respect good practices.

Naïf encoding of functions

Closures and continuations : code pointers

Closure

Points to the starting instruction of the **code of a function**

Continuation

Point to **the call-back** instruction of a running function call

Closures also contain the name of their arguments

Closures “are” the functions themselves.

Naive translation of functionsT

```

/*main code*/
...
f(42,x)
...
function f(y,z) {
/*code of f*/
...
}

```

becomes

```

# header
NewClot funf
DecArg y
DecArg z
SetVar f
...
# main code
...
getVar f
CstNb 42
SetArg
GetVar x
SetArg
...
Halt
#code of f
funf ...

```

Closure (1) :

function seen as a value

A closure is a value

- can be pushed on the stack,
- can be associated with a variable name,
- has a type in the machine (1).

It contains

- a pointer toward the code of the function,
- a stack of names for variables,
- ... (seen later)

NewClo off	Push(NewCloture{code = PC+off+1})	stk	l:stk
DclArg name	Pull.args.Push(name)	l:stk	l:stk
SetArg	Set(Pull.args.Pop, Pop)	v:l:stk	l:stk

Continuation (τ) :

return information (invisible)

A continuation is not a value

- can be pushed on the stack,
- but not manipulated in the context,
- it has a type τ but crashes on **TypeOf**.

It contains

- a pointer toward the line that called the function,
- ... (seen later)

(Continuation could be made values but would require to copy the stack.)

Call	<code>clot = Pop;</code> <code>Push(NewContinuation{code = PC})</code> <code>PC := clot.code</code>	<code>l:stk</code>	<code>t:stk</code>
Return	<code>res = Pop; PC := Pop.code; Push(res);</code>	<code>v:t:stk</code>	<code>v:stk</code>

Example : $y=f(5)$; function $f(x)$ {return $x+1$;}

11	: AddiNb
12	: RETURN

Why is x still in the contexte ??

we are not in f anymore, but x is local...

```
f --> closure[]
x --> 5
y --> 6
```

PILE

What makes a function call correct ?

Local variables are ephemeral

Local variables (and function arguments) should be local to the function.

Independant calls

Another call to the same function (sequential or recursive) should not interfere with local variable.

Muting global variables

A function can still see and modify global variables.

We definitely have to work with more contexts

Closures must refer to contexts

Closures and continuations contain pointers toward new contexts !

Managing local and global contexts

Solution 1:

Push variables on the stack

More efficient but heavy and do not go well with higher order.

Solution 2: New context for each function call

Lighter assembly code, but one has to manage context inclusion.

Our solution: Chained list of hash tables

- Still a dictionary,
- easy sharing sub-contexts (copy a pointeur),
- as many locality level as we need !

A new instructions do manage locality :

StrCall	<code>Pull.setContext(NewContext(CC))</code>	<code>l:stk</code>	<code>l:stk</code>
----------------	--	--------------------	--------------------

This extends the closure context with a new, “more local”, context.

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;}

Code

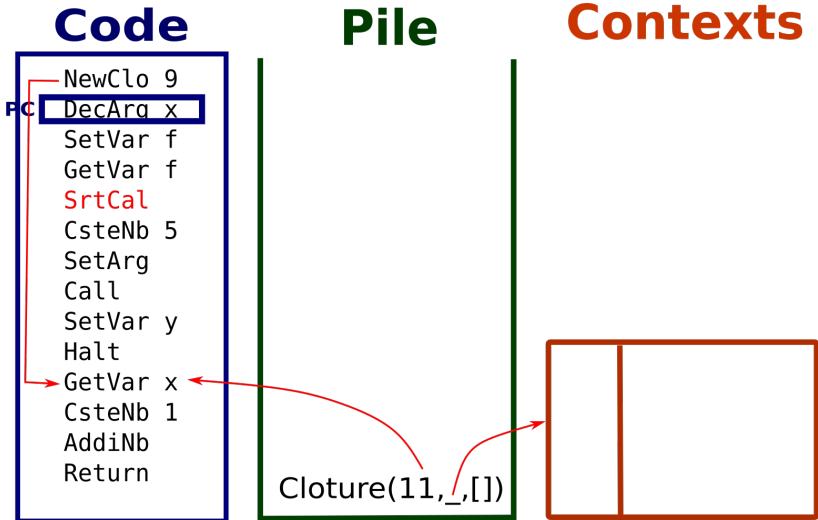

Pile

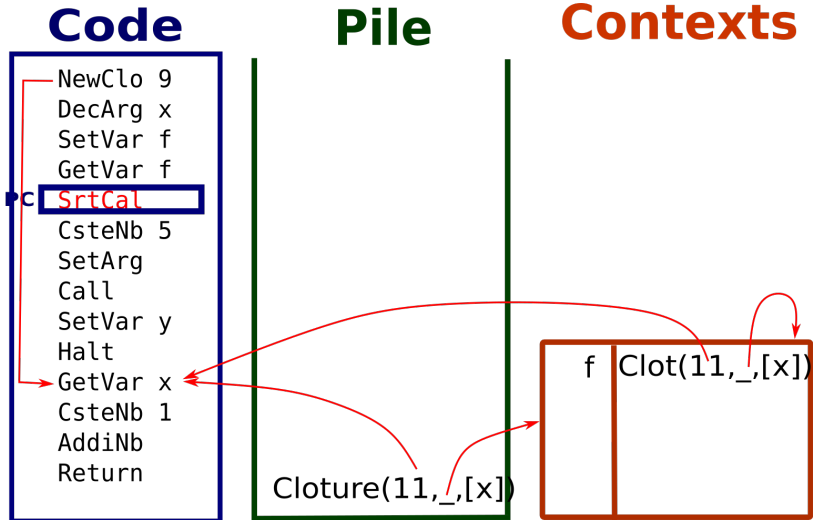

Contexts

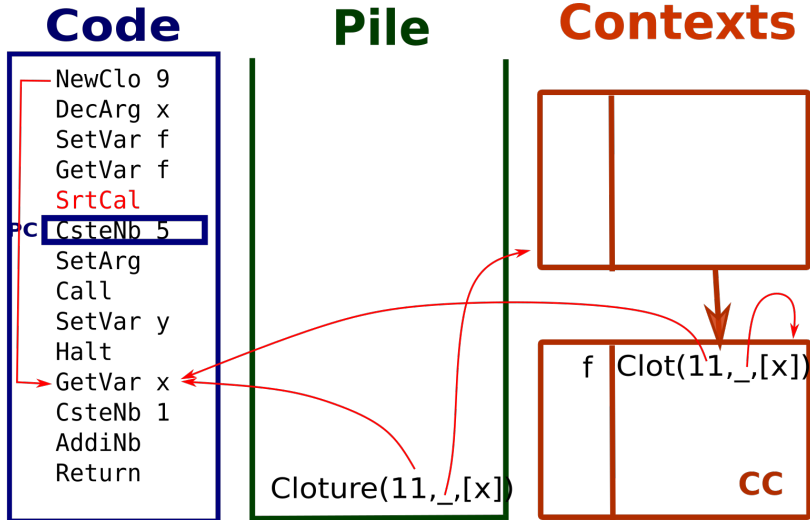

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;}

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;}

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;}

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;}

Code

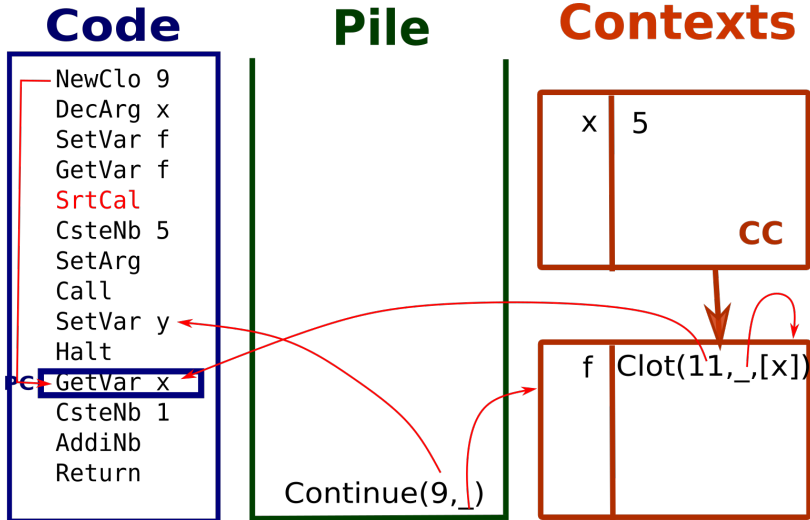

Pile

Contexts

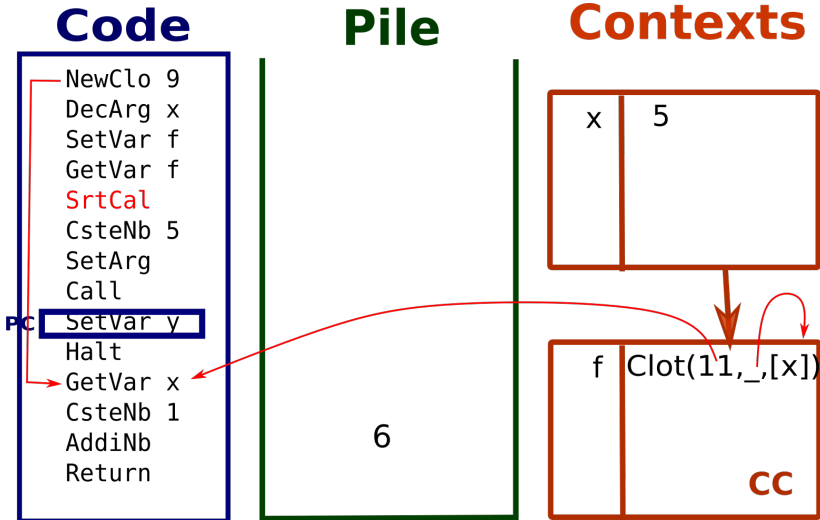

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;

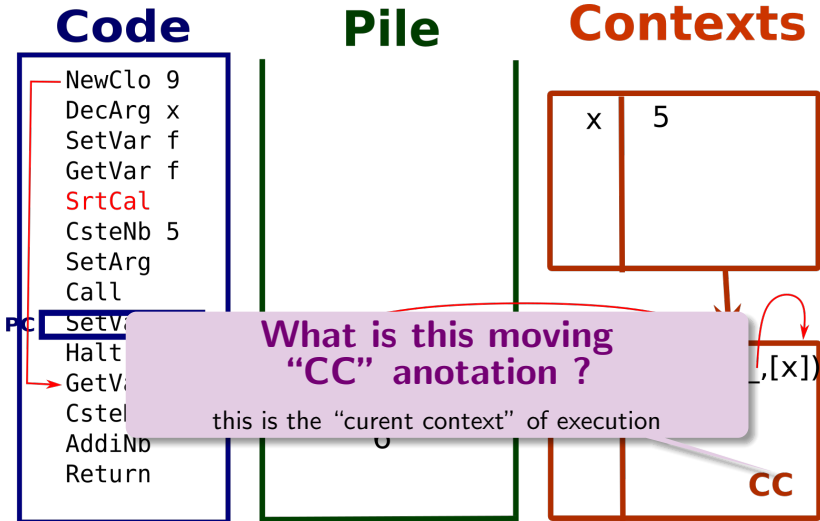

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;}

Correction : $y=f(5)$; function $f(x)$ {return $x+1$;

Closures (bis)

A closure contains

- a pointer toward the code of the function,
- a stack of names for variables,
- **a context**

NewClo off	Push(NewCloture{ code = PC+off+1, cont = CC })	stk	l:stk
StrCall	Pull.setContext(NewContext(CC))	l:stk	l:stk
DclArg name	Pull.args.Push(name)	l:stk	l:stk
SetArg	Set(Pull.args.Pop, Pop)	v:l:stk	l:stk

Continuation (bis)

A continuation contains

- a pointer toward the line that called the function,
- a **context**
- ... (more later)

Call	<pre> clot := Pop; Push(NewContinuation {code := PC, cont := CC}) PC := clot.code CC := clot.cont </pre>	l:stk	t:stk
Return	<pre> res := Pop; c := Pop; PC := c.code CC := c.cont; Push(res); </pre>	v:t:stk	v:stk

Demonstration on the VM

Notice the action of the garbage collector (GC) that remove the context.

Higher order + mutability : explosive cocktail

Exercice : Find the result of
the following program

```
g1 = f(1); g2 = f(0);  
g1(g1(g2(g2(10))));
```

```
function f(x) {  
  var y = x;  
  return g;  
  function g(z){  
    y = y+z;  
    return y;  
  }  
}
```

Higher order + mutability : explosive cocktail

Exercice : Find the result of
the following program

```
g1 = f(1); g2 = f(0);  
g1(g1(g2(g2(10))));
```

```
function f(x) {  
  var y = x;  
  return g;  
  function g(z){  
    y = y+z;  
    return y;  
  }  
}
```

42

Higher order + mutability : explosive cocktail

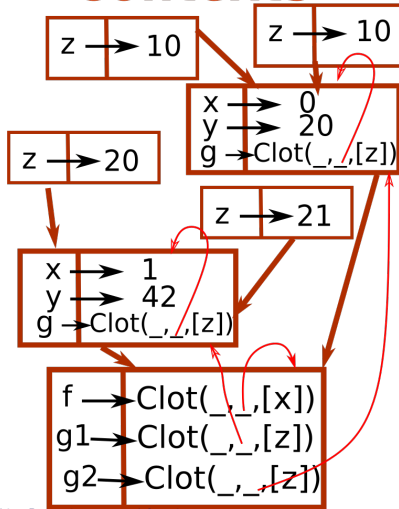

Exercice : Find the result of
the following program

```
g1 = f(1); g2 = f(0);
g1(g1(g2(g2(10))));
```

```
function f(x) {
  var y = x;
  return g;
  function g(z){
    y = y+z;
    return y;
  }
}
```

42

Contexts

Code generation: three distinct parts

Function calls

- context creation
- arguments instantiation
- call

Function code

- local var. declarations
- code
- returns

Header

- closure creation
- argument decl.
- function decl.

Remainder: JS Hoisting creates headers

- the declarations are hoisted as up as possible (header of the program/function).
- the function code is written in the end, after Halt (or remains where it is but with a Jump before)

Function call

$$\llbracket f(e_1, \dots, e_n) \rrbracket = \begin{array}{l} \llbracket f \rrbracket \\ \text{StrtCal} \\ \llbracket e_1 \rrbracket \\ \text{SetArg} \\ \vdots \\ \llbracket e_n \rrbracket \\ \text{SetArg} \\ \text{Call} \end{array}$$

StrCal	Pull.setContext(NewContext(CC))	l:stk	l:stk
SetArg	Set(Pull.args.Pop, Pop)	v:l:stk	l:stk
Call	clot = Pop; Push(NewContinue{code = PC, cont = CC}) PC := clot.code; CC := clot.cont	l:stk	t:stk

Optimisation : Tail Recursion

If the call is in tail position (argument of a return), then we can use the instruction T1Call that do not push the continuation, so that the previous one will be use to return from the new function.

Function code

Where to write the function code ?

- at the end of the program: cleaner but more difficult
- remains where it is: do not forget to add a Jump.

$$\llbracket \text{function } f(\dots)\{\text{code}\} \rrbracket = \text{label}_f \left| \begin{array}{l} \text{Jump} \\ \llbracket \text{code} \rrbracket \end{array} \right.$$

$$\llbracket \text{return } e; \rrbracket = \left| \begin{array}{l} \llbracket e \rrbracket \\ \text{Return} \end{array} \right.$$

Return	res = Pop; continu = Pop; PC := continu.code; CC := continu.cont; Push(res);	v:t:stk	v:stk
---------------	--	---------	-------

Header(s)

Where to write the header(s) ?

At the beginning of the program if the function is global,
at the beginning of the current function otherwise.

$\llbracket \text{function } f(x_1, \dots, x_n) \{ \dots \} \rrbracket =$

```

DecVar f
NewClo label_f
DecArg x1
  ⋮
DecArg xn
SetVar f

```

NewClo off	Push(NewCloture{ code = PC+off+1, cont = CC})	stk	l:stk
DclArg n	Pull.args.Push(n)	l:stk	l:stk

Example

```
g1 = f(1); g2 = f(0);
g1(g1(g2(g2(10))));
```

```
function f(x) {
  var y = x;
  return g;
  function g(z){
    y = y+z;
    return y;
  }
}
```

DecVar f	GetVar g1	#code f
NewClo 32	StrCal	DecVar y
DecArg x	GetVar g1	DecVar g
SerVar f	StrCal	NewClo 6
#tete fin	GetVar g2	DecArg z
GetVar f	StrCal	SetVar g
SrtCal	GetVar g2	GetVar x
CsteNb 1	StrCal	SetVar y
SetArg	CsteNb 10	GetVar g
Call	SetArg	Return
SetVar g1	Call	#code g
GetVar f	SetArg	GetVar y
SrtCal	Call	GetVar z
CsteNb 0	SetArg	AddiNb
SetArg	Call	SetVar y
Call	SetArg	GetVar y
SetVar g2	Call	Return
	Halt	

Example

Global header

declaration of f(x)

```
g1 = f(1); g2 = f(0);
g1(g1(g2(g2(10))));
```

```
function f(x) {
  var y = x;
  return g;
  function g(z){
    y = y+z;
    return y;
  }
}
```

DecVar f	GetVar g1	#code f
NewClo 32	StrCal	DecVar y
DecArg x	GetVar g1	DecVar g
SerVar f	StrCal	NewClo 6
#tete fin	GetVar g2	DecArg z
GetVar f	StrCal	SetVar g
SrtCal	GetVar g2	GetVar x
CsteNb 1	StrCal	SetVar y
SetArg	CsteNb 10	GetVar g
Call	SetArg	Return
SetVar g1	Call	#code g
GetVar f	SetArg	GetVar y
SrtCal	Call	GetVar z
CsteNb 0	SetArg	AddiNb
SetArg	Call	SetVar y
Call	SetArg	GetVar y
SetVar g2	Call	Return
	Halt	

Example

Code of f

```
g1 = f(1); g2 = f(0);
g1(g1(g2(g2(10))));
```

```
function f(x) {
  var y = x;
  return g;

Example

Header of f

decl. of y and g(z)

```
g1 = f(1); g2 = f(0);
g1(g1(g2(g2(10))));
```

```
function f(x) {
  var y = x;
  return g;
  function g(z){
    y = y+z;
    return y;
  }
}
```

DecVar f	GetVar g1	#code f
NewClo 32	StrCal	DecVar y
DecArg x	GetVar g1	DecVar g
SerVar f	StrCal	NewClo 6
#tete fin	GetVar g2	DecArg z
GetVar f	StrCal	SetVar g
SrtCal	GetVar g2	GetVar x
CsteNb 1	StrCal	SetVar y
SetArg	CsteNb 10	GetVar g
Call	SetArg	Return
SetVar g1	Call	#code g
GetVar f	SetArg	GetVar y
SrtCal	Call	GetVar z
CsteNb 0	SetArg	AddiNb
SetArg	Call	SetVar y
Call	SetArg	GetVar y
SetVar g2	Call	Return
	Halt	

Interlude : entrailles of GetVar and SetVar

Algorithm of Getvar x

Go down the contexts and return the value first found x
(or undefined if x not found)

```
GetVar x := CC.get(x)
c.get(x) := if (c.head.is_in(x)) return c.head.get(x);
           else if (c.is_bottom) return undefined;
           else return c.tail.get(x);
```

Algorithm of Setvar x

Go down the context and insert in the first found x
(or in the global context if x not found)

```
SetVar n x := CC.set(n,x)
c.set(n,x) := if (c.head.is_in(x)) c.head.set(n,x);
           else if (c.is_bottom) c.head.set(n,x);
           else c.tail.set(x);
```
