# Enforcing 3 by 3 Substitutions by Matching Rules 

Thomas Fernique

May 2023

## 3 by 3 substitutions

Map from colored tiles to $3 \times 3$ squares of them (finite colorset).

3 by 3 substitutions

A tiling is a grid of colored tiles which covers the whole plane.

## 3 by 3 substitutions

The substitution is said to define the set of tilings which admit an infinite sequence of preimages (also called hierarchical tilings).

## 3 by 3 substitutions

The substitution is said to define the set of tilings which admit an infinite sequence of preimages (also called hierarchical tilings).

## 3 by 3 substitutions

The substitution is said to define the set of tilings which admit an infinite sequence of preimages (also called hierarchical tilings).

## 3 by 3 substitutions

The substitution is said to define the set of tilings which admit an infinite sequence of preimages (also called hierarchical tilings).

## Matching rules

Consider a set of colored tiles.

## Matching rules

Tile's edges are decorated. A tile can yield several decorated tiles.

## Matching rules

Consider the tilings by translated tiles whose decorations match.

## Matching rules

Removing the decorations yields a set of tilings by colored tiles. These tilings are said to be enforced by the set of decorated tiles.

## Main result

Theorem
Given any 3 by 3 substitution, there exists a finite set of decorated tiles which enforces the set of tilings defined by this substitution.

## Main result

Theorem
Given any 3 by 3 substitution, there exists a finite set of decorated tiles which enforces the set of tilings defined by this substitution.

國 Thomas Fernique，Nicolas Ollinger，Combinatorial substitutions and sofic tilings（2010），11＋6pp．

We here follow the last proof，corrected and improved with the help of Nikolay Vereshchagin and Nikita Andrusov．

## Proof outline

We will define step by step:

- a finite set $\tau$ of decorated squares, where every edge is endowed with a (red,green,blue) triple of indices,
- a bijection $\phi$ from $3 \times 3$ squares of $\tau$-tiles to $\tau$-tiles,

## Proof outline

We will define step by step:

- a finite set $\tau$ of decorated squares, where every edge is endowed with a (red,green,blue) triple of indices,
- a bijection $\phi$ from $3 \times 3$ squares of $\tau$-tiles to $\tau$-tiles,
such that:
- every $\tau$-tiling can be uniquely partitioned into $3 \times 3$ squares,
- applying $\phi$ on these $3 \times 3$ squares ( + scaling) yields a $\tau$-tiling,
- there exist $\tau$-tilings.

## Proof outline

We will define step by step:

- a finite set $\tau$ of decorated squares, where every edge is endowed with a (red,green,blue) triple of indices,
- a bijection $\phi$ from $3 \times 3$ squares of $\tau$-tiles to $\tau$-tiles,
such that:
- every $\tau$-tiling can be uniquely partitioned into $3 \times 3$ squares,
- applying $\phi$ on these $3 \times 3$ squares ( + scaling) yields a $\tau$-tiling,
- there exist $\tau$-tilings.

The main theorem will then easily follow.

## Step 1: macro-tiles

Start with tiles $T_{1}, \ldots, T_{9}$.

## Step 1: macro-tiles

Start with tiles $T_{1}, \ldots, T_{9}$. Endow each edge with a red index enforcing the tiles to assemble into macro-tiles aligned along a grid.

## Step 1: macro-tiles

Start with tiles $T_{1}, \ldots, T_{9}$. Endow each edge with a red index enforcing the tiles to assemble into macro-tiles aligned along a grid.

## Step 2: rings and macro-macro-tiles

A green index $i \in\{1, \ldots, 9\}$ runs along a ring in every macro-tile.

## Step 2: rings and macro-macro-tiles

Further green indices force rings to order as $T_{i}$ 's in a macro-tile. ( $X_{i}$ denotes the red index on the $X$-edge of $T_{i}, X=N, W, S, E$ )

## Step 3: the network

A network carries green/blue indices from the central tile to ports.

## Step 3: the network

A network carries green/blue indices from the central tile to ports. Outside the network, the blue index just replicate the red one.

## Interlude: the map $\phi$

$\phi$ maps the green indices forcing ring ordering onto red indices and copies the green/blue indices from network branches.

## Interlude: the map $\phi$

$\phi$ maps the green indices forcing ring ordering onto red indices and copies the green/blue indices from network branches.

## Interlude: the map $\phi$

$\phi$ maps a tiling onto a tiling. Does it map a $\tau$-tiling onto a $\tau$-tiling? The indices on the network will have to be chosen so that it holds.

## Step 4: ring/network intersections

When a ring along which runs $j$ crosses an $X$-branch, it checks that the pair carried by the branch is allowed on the $X$-edge of $T_{j}$.

For e.g. a North-branch:

## Step 4: ring/network intersections

When a ring along which runs $j$ crosses an $X$-branch, it checks that the pair carried by the branch is allowed on the $X$-edge of $T_{j}$.

For e.g. a North-branch:

- $j \in\{1,3\} \rightsquigarrow\{M, P, 14,25,36,47,58,69\} \times\{M\} ;$

## Step 4: ring/network intersections

When a ring along which runs $j$ crosses an $X$-branch, it checks that the pair carried by the branch is allowed on the $X$-edge of $T_{j}$.

For e.g. a North-branch:

- $j \in\{1,3\} \rightsquigarrow\{M, P, 14,25,36,47,58,69\} \times\{M\}$;
- $j \in\{4,6,7,9\} \rightsquigarrow\{1, \ldots, 9\} \times\left\{N_{j}\right\}$;

## Step 4: ring/network intersections

When a ring along which runs $j$ crosses an $X$-branch, it checks that the pair carried by the branch is allowed on the $X$-edge of $T_{j}$.

For e.g. a North-branch:

- $j \in\{1,3\} \rightsquigarrow\{M, P, 14,25,36,47,58,69\} \times\{M\}$;
- $j \in\{4,6,7,9\} \rightsquigarrow\{1, \ldots, 9\} \times\left\{N_{j}\right\}$;
- $j \in\{2,5,8\} \rightsquigarrow$ every pair already defined on any north-edge!

## Step 4: ring/network intersections

When a ring along which runs $j$ crosses an $X$-branch, it checks that the pair carried by the branch is allowed on the $X$-edge of $T_{j}$.

For e.g. a North-branch:

- $j \in\{1,3\} \rightsquigarrow\{M, P, 14,25,36,47,58,69\} \times\{M\} ;$
- $j \in\{4,6,7,9\} \rightsquigarrow\{1, \ldots, 9\} \times\left\{N_{j}\right\}$;
- $j \in\{2,5,8\} \rightsquigarrow$ every pair already defined on any north-edge!

This yields $2 \times 8+4 \times 9+3 \times 6 \times 9=214$ decorated $T_{2}$.
Together with $T_{4,6,8}$ (214 each) and $T_{1,3,7,9}$ (9 each): 892 tiles.

## Step 5: synchronizing network branches

Pairs on $X$ - and $Y$-branches could be allowed on $X$ - and $Y$-edges of different decorated $T_{j}$. The branches have to be synchronized.

## Step 5: synchronizing network branches

This is done by allowing on $T_{5}$ the pairs of every non-central tile.

## Step 5: synchronizing network branches

This is done by allowing on $T_{5}$ the pairs of every non-central tile. This double the number of tiles: there are thus $1784 \tau$-tiles in all.

## Back to the map $\phi$

$\phi$ maps any $\tau$-macro-tile with $i$ on the ring onto a decorated $T_{i}$. But why should it be a $\tau$-tile?

## Back to the map $\phi$

The decorated $T_{j}$ the central tile is derived from (Step 5) is in $\tau$. We claim that it is one and the same tile, except if $i=5$.

## Back to the map $\phi$

When the ring intersects an $X$-branch of the network, it forces the green/blue pair to be allowed on some decorated $T_{i}$ (Step 4).

## Back to the map $\phi$

If the $X$-edge of $T_{i}$ is not on the network of the macro-tile, then its blue index replicates its red one (Step 3).

## Back to the map $\phi$

A red index (other than $M$ ) determines $i($ Step 1$)$, whence $i=j$.

## Back to the map $\phi$

This fails for $i=5$ because the network crosses every edge of $T_{5}$. But in this case, $\phi$ simply maps the macro-tile onto its central tile!

## Back to the map $\phi$

Whatever $i$ on the ring, $\phi$ thus maps the $\tau$-macro-tile onto a $\tau$-tile. It is moreover a bijection: the inverse function is straightforward.

## Back to the map $\phi$

In particular, applying ad infinitum $\phi^{-1}$ to any $\tau$-tile yields arbitrarily large $\tau$-patches, hence a $\tau$-tiling by compacity.

## Back to the map $\phi$

In particular, applying ad infinitum $\phi^{-1}$ to any $\tau$-tile yields arbitrarily large $\tau$-patches, hence a $\tau$-tiling by compacity.

Back to the map $\phi$

In particular, applying ad infinitum $\phi^{-1}$ to any $\tau$-tile yields arbitrarily large $\tau$-patches, hence a $\tau$-tiling by compacity.

## Proof of the theorem

We use $\tau$ tiles to enforce a given $3 \times 3$ substitution.
The $T_{i}$ 's come in colors (those appearing in the substitution).
The ring indices as well.
The color of a $\tau$-tile is determined w.r.t. the substitution by

- its position in the macro-tile (given by its red indices)
- the color on the ring (green index if $i \neq 5$, blue ones if $i=5$ ).
