# Motivation

- Dynamical systems:
  - in which a function describes the time dependence of a point in a geometrical space.
  - we only know certain observed or calculated states of its past or present state.
  - dynamical systems have a direct impact on human development.
- $\Rightarrow$  The importance of studying:
  - synchronization
  - behavior
  - robust control

# Robustness

- A control is considered robust if the dynamical system still stable, which means small perturbations to the solution using this control lead to a new solution that stays close to the original solution forever.
- A stable system produces a bounded output for a given bounded input.

|            |   |                                 |                                  |                             |

# An invariant

- The bounded output of some periodic stable system that is generated by a periodic robust control can be considered as an invariant from certain t.
- An invariant is an unchanged object after operations applied to it.

## Description of the method

Given a differential system  $\Sigma : dy/dt = f_u(y)$  of dimension *n* controlled by *u*, an initial point  $y_0 \in \mathbb{R}^n$ , a real  $\varepsilon > 0$ , and a ball  $B_0 = B(y_0, \varepsilon)^1$ 

The center of each ball at time *t* is the Euler approximate solution  $\tilde{Y}_{y_0}^u(t)$  of the system starting at  $y_0$ , and the radius is a function  $\delta_{\varepsilon}^u(t)$  bounding the distance between  $\tilde{Y}_{y_0}^u(t)$  and an exact solution  $Y_{y_0}^u(t)$  starting at  $B_0$ .

| Motivation | Problematic and description of the method | Euler's method and error bounds | Systems with bounded uncertainty | Biochemical process example |

|            | 00  |                                 |                                  |                             |
|            |   |                                 |                                  |                             |

## Description of the method

Given a differential system  $\Sigma : dy/dt = f_u(y)$  of dimension *n* controlled by *u*, an initial point  $y_0 \in \mathbb{R}^n$ , a real  $\varepsilon > 0$ , and a ball  $B_0 = B(y_0, \varepsilon)^1$ 

■ To find a *bounded* invariant, we look for a positive real *T* such that  $B((i + 1)T) \subseteq B(iT)$  for some  $i \in \mathbb{N}$ . In case of success, the ball B(iT) is guaranteed to contain the "stroboscopic" sequence  $\{B(jT)\}_{j=i,i+1,...}$  of sets B(t) at time t = iT, (i + 1)T, ... and thus constitutes the sought bounded invariant set.

<sup>1</sup> $B(y_0, \varepsilon)$  is the set  $\{z \in \mathbb{R}^n \mid ||z - y_0|| \le \varepsilon\}$  where  $||\cdot||$  denotes the Euclidean distance.

|            |   |                                 |                                  |                             |

## Euler's method and error bounds

Let us consider the differential system controlled by *u*:

$$\frac{dy(t)}{dt}=f_u(y(t)).$$

where  $f_u(y(t))$  stands for  $f(\mathbf{u}(t), y(t))$  with  $\mathbf{u}(t) = u$  for  $t \in [0, \tau]$ , and  $y(t) \in \mathbb{R}^n$  denotes the state of the system at time *t* where  $\tau$  is the integration time-step.

- $Y_{y_0}^u(t)$  denotes the exact continuous solution *y* of the system at time  $t \in [0, \tau]$  under constant control *u*, with initial condition *y*<sub>0</sub>.
- $\tilde{Y}_{y_0}^u(t) \equiv y_0 + tf_u(y_0)$  denotes Euler's approximate value of  $Y_{y_0}^u(t)$  for  $t \in [0, \tau]$ .

| Motivation | Problematic and description of the method | Euler's method and error bounds | Systems with bounded uncertainty | Biochemical process example |
|------------|---|---------------------------------|----------------------------------|-----------------------------|
|            |   | 00000                           |                                  |                             |
|            |   |                                 |                                  |                             |

## Finite horizon and dynamic programming

Let us explain the principle of the method to find a control pattern  $\pi \in U^k$  based on DP and Euler integration method used in [CF19a; CF19b]. Given  $k \in \mathbb{N}$  and  $\tau \in \mathbb{R}_{>0}$ , we consider the following *finite time horizon optimal control* 

Given  $k \in \mathbb{N}$  and  $\tau \in \mathbb{R}_{>0}$ , we consider the following *finite time horizon optimal control problem*: Find for each  $y \in S$ 

• the value  $\mathbf{v}_k(y)$ , i.e.,

$$\mathbf{v}_{k}(y) = \min_{\pi \in U^{k}} \left\{ J_{k}(y,\pi) \right\} \equiv \min_{\pi \in U^{k}} \left\{ \| Y_{y}^{\pi}(k\tau) - y_{end} \| \right\}.$$

and an *optimal pattern*:

$$\pi_k(\mathbf{y}) := \arg\min_{\pi \in U^k} \big\{ \| Y_{\mathbf{y}}^{\pi}(k\tau) - \mathbf{y}_{end} \| \big\}.$$

The space S is discretized by means of a grid  $\mathcal{X}$  such that any point  $y_0 \in S$  has an " $\varepsilon$ -representative"  $z_0 \in \mathcal{X}$ . This method is generated by a procedure  $PROC_k^{\varepsilon}$  which, for any  $y \in S$ , takes its representative  $z \in \mathcal{X}$  as input, and returns a pattern  $\pi_k^{\varepsilon} \in U^k$  corresponding to an approximate optimal value of  $\mathbf{v}_k(y)$  (see [CF19b]).

#### Proposition

[LCDVCF17] Consider the solution  $Y_{y_0}^u(t)$  of  $\frac{dy}{dt} = f_u(y)$  with initial condition  $y_0$  of  $\varepsilon$ -representative  $z_0$  (hence such that  $||y_0 - z_0|| \le \varepsilon$ ), and the approximate solution  $\tilde{Y}_{z_0}^u(t)$  given by the explicit Euler scheme. For all  $t \in [0, \tau]$ , we have:

 $\|Y_{y_0}^u(t) - \tilde{Y}_{z_0}^u(t)\| \leq \delta_{\varepsilon}^u(t).$

#### Definition

*L<sub>u</sub>* denotes the Lipschitz constant for *f<sub>u</sub>*, and  $\lambda_u$  is the "one-sided Lipschitz constant" (or "logarithmic Lipschitz constant" [AS14]) associated to *f<sub>u</sub>*, i. e., the minimal constant such that, for all *y*<sub>1</sub>, *y*<sub>2</sub>  $\in S$ :

$$\langle f_u(y_1) - f_u(y_2), y_1 - y_2 \rangle \leq \lambda_u \|y_1 - y_2\|^2,$$
 (H0)

where  $\langle \cdot, \cdot \rangle$  denotes the scalar product of two vectors of  $\mathcal{S}.$ 

The constant  $\lambda_u$  can be computed using a nonlinear optimization solver (e.g., CPLEX [Cpl09]) or using the Jacobian matrix of *f*.

|            |   |                                 |                                  |                             |

## Systems with bounded uncertainty

A differential system with bounded uncertainty is of the form

$$\frac{dy(t)}{dt}=f_u(y(t),w(t)),$$

with  $t \in \mathbb{R}^n \ge 0$ , states  $y(t) \in \mathbb{R}^n$ , and uncertainty  $w(t) \in \mathcal{W} \subset \mathbb{R}^n$  ( $\mathcal{W}$  is compact, i.e., closed and bounded).

■ We suppose (see [LCADSC+17]) that there exist constants  $\lambda_u \in \mathbb{R}$  and  $\gamma_u \in \mathbb{R}_{\geq 0}$  such that, for all  $y_1, y_2 \in S$  and  $w_1, w_2 \in \mathcal{W}$ :

$$\langle f_u(y_1, w_1) - f_u(y_2, w_2), y_1 - y_2 \rangle \leq \lambda_u ||y_1 - y_2||^2 + \gamma_u ||y_1 - y_2|| ||w_1 - w_2||$$
 (H1).

Instead of computing  $\lambda$  and  $\gamma$  globally for S, it is advantageous to compute them *locally* depending on the subregion of S occupied by the system state during a considered interval of time.

## Biochemical process example

Consider a biochemical process model *Y* of continuous culture fermentation (see [HLID09]) and initial condition in  $B_0 = B(x_0, \varepsilon)$  for some  $x_0 \in \mathbb{R}^2$  and  $\varepsilon > 0$  (see [BQ20]):. Let  $Y = (X, S, P) \in \mathbb{R}^3$  satisfies the differential system:

$$\begin{aligned} \int \frac{dX}{dt} &= -DX(t) + \mu(t)X(t) \\ \frac{dS}{dt} &= D(S_f(t) - S(t)) - \frac{\mu(t)X(t)}{Y_{X/S}} \\ \frac{dF}{dt} &= -DP + (\alpha\mu(t) + \beta)X(t) \end{aligned}$$

where *X* denotes the biomass concentration, *S* the substrate concentration, and *P* the product concentration of a continuous fermentation process. The model is controlled by  $S_f \in [S_f^{min}, S_f^{max}]$ . While the dilution rate *D*, the biomass yield  $Y_{x/s}$ , and the product yield parameters  $\alpha$  and  $\beta$  are assumed to be constant and thus independent of the actual operating condition, the specific growth rate  $\mu : \mathbb{R} \to \mathbb{R}$  of the biomass is a function of the states:

$$\mu(t) = \mu_m \frac{\left(1 - \frac{P(t)}{P_m}\right)S(t)}{K_m + S(t) + \frac{S(t)^2}{K_i}}$$

## **Conclusion and Perspectives**

#### Conclusion

- We presented a simple method to generate a bounded invariant for a differential system.
- We have given a simple condition which guarantees that, under a repeated control sequence the system with perturbation is robust.
- The method uses a simple algorithm to compute local rates of contraction in the framework of Euler's method.
- The method uses a very general criterion of inclusion of one set in another.

#### Perspectives

Extend our method in order to take into account the specification of state constraints during the evolution of the system.
